WORKERS' EXPOSURE TO AI ACROSS DEVELOPMENT[•]

Piotr Lewandowski*, Karol Madoń*, Albert Park*

Abstract

This paper develops a task-adjusted, country-specific measure of workers' exposure to artificial intelligence (AI) across 108 countries, covering approximately 89% of global employment. Building on the AI Occupational Exposure index by Felten et al. (2021), we map AI-related abilities to worker-level tasks using survey data from PIAAC, STEP, and CULS. We then predict occupational AI exposure in countries lacking survey data using a regression-based approach. Our findings show that accounting for within-occupation task differences significantly amplifies the development gradient in AI exposure. About 49% of cross-country variation is explained by differences in task content, particularly among high-skilled occupations. We attribute these differences primarily to cross-country differences in ICT use intensity, followed by human capital and globalisation-related firm characteristic. We also document rising AI exposure over the past decade, driven largely by changes in task composition. Our results highlight the central role of digital infrastructure and skill use in shaping global AI exposure.

1. Introduction

The rapid progress of large language models (LLMs) and generative AI (GenAI) has attracted significant public attention, particularly due to concerns about potential labour displacement. Empirical analysis of GenAI's labour market effects, however, has been limited by the scarcity of systematic data on AI investment and application. In response, researchers have turned to measuring workers' exposure to AI, typically combining patent data with occupational task information (Felten et al., 2021, 2018; Gmyrek et al., 2023; Webb, 2020). Most of this work focuses on the United States, leveraging detailed occupation-level data from the Occupational Information Network (O*NET). Yet, occupational tasks differ significantly across countries due to variation in technology use, skill supply, and participation in global value chains (Caunedo et al., 2023; Lewandowski et al., 2022). A key question is whether AI exposure varies across development levels and what factors drive these differences.

This paper provides a reliable measure of Artificial Intelligence (AI) exposure that accounts for task differences across countries at different development levels. We build upon the task approach to studying the interplay between technology and labour (Acemoglu and Autor, 2011; Autor, 2013). To measure the relationship between job tasks and exposure to AI, we combine the well-established Artificial Intelligence Occupational Exposure (AIOE) of Felten et al. (2021) with the worker-level survey data from the OECD's Programme for the International Assessment of Adult Competencies (PIAAC), World Bank's Skills towards Employment Programme (STEP), and China Urban Labor Survey (CULS) which jointly cover 53 countries across all development levels. First, we identify PIAAC survey questions that best map AI capabilities to U.S. occupations. Next, we apply the same question sets to compute AI exposure in other countries included in the STEP, PIAAC, and CULS surveys. Finally, we use regression models to examine factors associated with cross-country variation in AI exposure— particularly within similar occupations—and to predict occupational exposure in countries lacking survey data. In total, we estimate occupational AI exposure for 108 countries, representing approximately 89% of global employment, enabling cross-country comparisons across the development spectrum.

This study makes four main contributions. First, we create country-specific AI exposure measures that reflect differences in tasks across a broad set of economies. Our regression-based method links O*NET ability requirements to PIAAC-reported job tasks, adapting the AIOE index to U.S. worker-level data and extending it globally. While prior work measured AI exposure using occupational tasks (Gmyrek et al., 2025, 2023; Webb, 2020) or abilities (Felten et al., 2021), these studies produced occupation-level estimates uniform across countries. Gmyrek et al. (2024) adjusted AI exposure with expected computer access in Latin America, but, to our knowledge, this is the first study to rely on country-specific data on job tasks and skill use at work to produce internationally comparable, task-based measures of AI exposure.

Second, we document substantial heterogeneity in AI exposure across countries and occupations. Workers' AI exposure increases strongly with development level, both overall and within occupations. Decomposing crosscountry variation, we find that differences in tasks explain approximately 49% of the observed variance, with remaining variation attributable to differences in occupational structures. Adjusting for task variation within occupations significantly amplifies cross-country disparities, especially in low- and middle-income countries and within high-skilled occupations such as managers, professionals, and technicians. Using two waves of PIAAC data for high-income countries, we also show that AI exposure has risen since the early 2010s, primarily due to changes in within-occupation task structures, underscoring the need to account for task content in exposure estimates. Third, we identify key worker-level correlates of AI exposure. Greater ICT intensity at the country-sector level is positively associated with exposure, while higher integration in the globalised economy—measured by forward linkages in global value chains and FDI inflows—is negatively associated. Our use of workers' cognitive skill measures, such as literacy proficiency, enables us to account for international variation in education quality. We find that both education and cognitive skills are positively correlated with AI exposure. This has important distributional implications: if AI substitutes for skilled labour, it could reduce inequality; if it complements skilled labour, inequality may increase. By capturing the positive relationship between individuals' human capital and worker-level AI exposure, we go beyond existing research that often compares socio-economic groups based only on occupational composition, overlooking task-level variation and differences in actual skill levels (Cazzaniga et al., 2024; Comunale and Manera, 2024; Pizzinelli et al., 2023).

We further decompose cross-country exposure differences using our regression results and find that ICT intensity, notably higher in more developed countries, accounts for 33–52% of the cross-country variance in workers' AI exposure. Occupational composition (12.2%), human capital (10.7%), and firm-level characteristics (4.4%) play smaller roles. Using various measures of ICT infrastructure, we confirm that digital usage and capabilities are key drivers of cross-country variation in AI exposure. Thus, our findings align with prior literature showing that more developed countries use skilled labour more efficiently thanks to adopting more technologies, such as ICT, that complement skilled work (Caselli and Coleman, 2006). We acknowledge that the cross-country differences in ICT adoption can partly depend on the international differences in the supply of skilled labour (Eden and Gaggl, 2020), which are substantial and largely reflect schooling quality (Angrist et al., 2021; Hendricks and Schoellman, 2018; Martellini et al., 2024). However, we do control for test-based measures of human capital, which capture cross-country differences in schooling quality. Moreover, micro-data-based evidence identifies the cross-country differences in the skill bias of technology as a much more powerful force behind the international differences in skill premia than the differences in the relative human capital of skilled labour (Rossi, 2022). This supports our interpretation of ICT being the key fundamental factor explaining large international differences in AI exposure, with human capital contributing much less.

Fourth, we extend our estimates to 55 additional countries lacking survey data. Estimating occupation-specific regressions for countries with survey data, we predict occupational AI exposure values at the 1- and 2-digit levels of the International Standard Classification of Occupations (ISCO-08) based on countries' endowments and technology readiness. This expands our coverage to 108 countries, encompassing roughly 89% of global employment. Our results show that the top quartile of AI-exposed workers is concentrated in high-income countries, while the bottom quartile is concentrated in low- and middle-income countries. These findings challenge narratives of uniform global AI impact and suggest that high-income countries are likely to experience the greatest short-term effects.

This paper is structured as follows. Section 2 introduces the data, measurements, and methodology. Section 3 presents our results and stylised facts on global disparities in workers' AI exposure. Section 4 concludes.

2. Data and AI exposure measurement

2.1. Data for measurement of AI exposure

To construct worker-level measures of AI exposure, we combine data from the O*NET occupational abilities database with U.S. data from the OECD's Programme for the International Assessment of Adult Competencies (2019). O*NET, widely used in academic research on task content (Acemoglu and Autor, 2011; Autor and Handel, 2013) characterises U.S. occupations through 52 defined abilities, quantifying their importance (on a 1-5 scale) and level (on a 1-7 scale). Examples are provided in Table A1.

PIAAC is a large-scale international survey that assesses adults' proficiency in cognitive skills, job tasks, and skill use at work across countries. It includes a broad set of work-related questions covering literacy, numeracy, problem-solving, interpersonal tasks, and types of computer use.

To extend the analysis beyond the U.S., we construct a cross-country, worker-level dataset spanning 53 countries at varying stages of development (Appendix Table A4). The core of this dataset comes from PIAAC, which collected data across two cycles. The first cycle includes three waves (2011–2012, 2014–2015, 2017–2018) in 37 countries, each with samples of several thousand individuals aged 16–65. At the time of writing, the second PIAAC cycle, collected in 2022-2023, provides research-quality data for 18 countries, 14 of which participated in the first cycle and in both provide occupational information at the 2-digit level of ISCO-08.¹ We supplement PIAAC with data from the World Bank's Skills Toward Employment and Productivity survey – STEP (World Bank, 2017), covering 12 low- and middle-income countries with urban samples of individuals aged 15–64, collected between 2012 and 2014. As STEP surveys exclude rural populations, we omit ISCO 6 (skilled agricultural workers and farmers) in all countries for consistency. We also incorporate two waves of the China Urban Labor Survey (CULS), conducted in 2016 and 2023 by the Chinese Academy of Social Sciences. CULS includes a task module consistent with PIAAC and STEP. Following Lewandowski et al. (2022), we reweigh the data so the occupational structures align with those based on LFS surveys and ILOSTAT statistics.

2.2. Abilities selection

The AI exposure index developed by Felten et al. (2021) is based on occupational abilities from O*NET. To derive worker-level exposures from task data, we use U.S. PIAAC survey responses to approximate the distribution of these abilities across occupations in the U.S. Specifically, we identify 24 O*NET abilities—out of the 52 used by Felten et al. (2021)—that can be proxied using PIAAC questions on job tasks.² On average, these 24 abilities account for 67% of the total weight across O*NET occupations, while the remaining 28—primarily physical abilities such as trunk strength and multi-limb coordination—account for 33%. As these physical abilities are less likely to be affected by AI, we focus on the subset more relevant to AI-related task transformation.

We replicate the original AIOE index using only the 24 abilities which can be proxied with PIAAC questions and find that the results are nearly identical to those based on the full set of abilities. The correlation between such

¹ Belgium, Chile, Czechia, France, Hungary, Israel, Italy, Japan, Poland, Singapore, Slovakia, South Korea, Spain, and the United States.

² For the list and detailed description of abilities, see Table A1 in the Appendix A.

modified AIOE scores and the values provided by Felten et al. (2021) is 0.98 (Appendix Figure B1), confirming the robustness of this approach.

2.3. Approximation of O*NET abilities with US PIAAC data

To approximate O*NET abilities using PIAAC data, we adopt a regression-based strategy. We utilise 18 PIAAC questions: 15 related to routine and non-routine task content (following Lewandowski et al., 2022) and three additional questions capturing ICT use and time management (Tables 1-2).³ For each ability, we identify the optimal set of PIAAC questions that best reproduces the cross-occupational distribution of that ability at the ISCO 2-digit level in the U.S. To ensure reliability, the algorithm selects between three and eight questions per ability and limits inter-question correlation to below 0.3 to reduce multicollinearity. The selected questions exhibit the highest correlations with the importance of each ability across occupations (see Table 1 for questions phrasing and Table 2 for their matching).

Table 1. The list of PIAAC questions selected to proxy for O*NET abilities

- Q1 Do you manage or supervise other employees?
- Q2 The next few questions are about the amount of flexibility you have in deciding how you do your job: To what extent can you choose or change the sequence of your tasks?
- Q3 In your job, what proportion of your time do you usually spend cooperating or collaborating with coworkers?
- Q4 How often does your job usually involve making speeches or giving presentations in front of five or more people?
- Q5 How often does your job usually involve planning your own activities?
- Q6 How often does your job usually involve organising your own time?
- Q7 And how often are you usually confronted with more complex problems that take at least 30 minutes to find a good solution? The 30 minutes only refers to the time needed to THINK of a solution, not the time needed to carry it out.
- Q8 How often does your job usually involve working physically for a long period?
- Q9 In your job, how often do you usually read articles in newspapers, magazines or newsletters?
- Q10 In your job, how often do you usually read articles in professional journals or scholarly publications?
- Q11 In your job, how often do you usually read manuals or reference materials?
- Q12 In your job, how often do you usually read bills, invoices, bank statements or other financial statements?
- Q13 In your job, how often do you usually fill in forms?
- Q14 In your job, how often do you usually calculate prices, costs or budgets?
- Q15 In your job, how often do you usually use more advanced math or statistics such as calculus, complex algebra, trigonometry or use of regression techniques?
- Q16 In your job, how often do you usually use email?
- Q17 In your job, how often do you usually use spreadsheet software, for example Excel?
- Q18 In your job, how often do you usually use a programming language to program or write computer code?

Table 2. The PIAAC questions with the highest correlation with O*NET abilities (importance) in the US

Source: own elaboration on PIAAC and O*NET data.

We then estimate the importance of each ability through regression, using the selected PIAAC questions as predictors. For each of the 24 O*NET abilities, we estimate the following specification:

$$Y_{a,o} = \sum_{n}^{N} \beta_n Q_{i,o}^n + \epsilon_{i,o} \tag{1}$$

where $Y_{a,o}$ is the O*NET importance of ability a in occupation o, and $Q_{i,o}^n$ denotes the answers of individual i to question n, who is employed in occupation o. We treat all question responses as categorical variables in a nonparametric framework. For instance, if responses are given on a 1–5 scale, we use indicator variables for values 2 through 5, with 1 as the reference category.

Notably, variation in dependent variable $Y_{a,o}$ is at the occupation level, while variation in the explanatory variables occurs at the worker level, allowing us to capture within-occupation heterogeneity. While an alternative approach would involve aggregating survey responses at the occupational level, our worker-level model enables the construction of individual-level AI exposure measures and allows us to quantify variation within occupations.

We first estimate regression coefficients for each PIAAC question response using U.S. data (Tables B1–B4 in Appendix B).⁴ These coefficients are then applied to calculate predicted ability levels at the individual level across all countries in the PIAAC dataset. For the U.S, this approach yields a high correlation (94.1%) between the model-predicted importance of abilities and the original O*NET-based importance scores.

Next, we follow a procedure analogous to Felten et al. (2021) to construct AI exposure measures (AIOE), substituting PIAAC-based approximated abilities for the original O*NET weights. This allows us to replicate the distribution of AIOE scores across occupations in the U.S. with considerable accuracy. The correlation between our PIAAC-based AIOE estimates and the original Felten et al. (2021) AIOE index is 87% across 2-digit ISCO occupations in the U.S. (Figure 2). The correlation between our measure and other widely-used measure of AI exposure, namely occupational exposure to generative pretrained transformers (GPTs) proposed by Eloundou et al. (2024) is also high, also amounts to 87% across 2-digit ISCO occupations in the US (Appendix Figure B3).⁵

For a detailed decomposition of within-country AI exposures by specific task items (PIAAC and STEP questions), see the "Variance Decomposition" subsection in Appendix B.

⁴ For corresponding estimates for STEP/ CULS see Tables B5-B8 in Appendix B. See Table A3 in Appendix A for correspondence between PIAAC and STEP/ CULS questions.

⁵ The correlation between Felten et al. (2021) and by Eloundou et al. (2024) exposure measures is 95% across 2-digit ISCO occupations in the US.

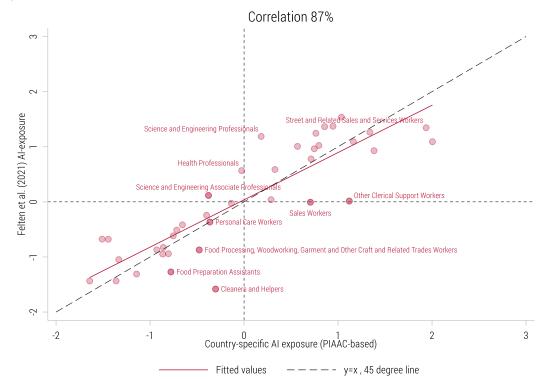

Figure 1. The correlation between AIOE calculated for the US with O*NET abilities and with PIAAC survey data

Notes: Appendix Table A2 presents a detailed list of ISCO08 2-digit occupations. See Appendix Figure B2 for the decomposition of the difference between Felten et al. (2021) and PIAAC-based AI exposures. See Appendix Figure B3 for the correlation between Eloundou et al. (2024) GPT exposure and our PIAAC-based AI exposures. Source: own elaboration based on Felten et al. (2021) and PIAAC data.

2.4. Econometric methodology

To examine the determinants of variation in AI exposure, we estimate OLS regressions at the worker level:

$$AIE_{ijsc} = \beta_0 + \beta_1 T_{sc} + \beta_2 H_{ijsc} + \tau_o + \beta_3 F_{sc} + \beta_4 D_c + \delta_c^{2022} + \varepsilon_{ijsc}$$
⁽²⁾

where, AIE_{ijsc} denotes the AI exposure of worker *i* in occupation *j* in sector *s* in country *c*, T_{sc} captures the ICT intensity in sector *s* in country *c*, H_{ijsc} represents individual-level human capital, τ_o are occupation fixed effects, F_{sc} denotes firm characteristics in sector *s* in country *c* (including sector fixed effects), D_c comprises development indicators measured at the country level, also interacted with sector fixed effects, and δ_c^{2022} is a fixed effect for the second PIAAC cycle (in the discussion of results in subsection 3.2, we call it "time-trend").

We operationalise the key variables as follows (Table 3 provides details on data sources):

- ICT intensity: measured as the share of workers using computers at the country-sector level, including a squared term to capture non-linear effects.
- Human capital: includes worker-level variables such as educational attainment, test-based literacy
 proficiency (four levels), gender, and age (in 10-year groups).
- Occupational structure: controlled for using 2-digit ISCO fixed effects.

- Firm characteristics: include the share of firms with owning websites, share of firms using technology licensed from foreign companies, share of firms with internationally recognised quality certificate, and both forward and backward participation in global value chains, measured at the country-sector level of International Standard Industrial Classification (ISIC Rev.4), along with 1-digit ISIC sector fixed effects.
- Development indicators: the baseline specification uses the (demeaned) log of GDP per capita (PPP) as a proxy for development level and its interaction with country-sector fixed effects. Alternative specifications substitute GDP with learning-adjusted years of schooling, the Human Capital Index, tertiary enrolment rate, ICT Development Index, digital readiness score, or urbanisation rate.⁶

Variable	Source
Technology	
ICT intensity – share of workers using computers by sector-country	PIAAC/ STEP
Share of the population with internet access	World Development Indicators (WDI)
ICT development index (IDI)	ITU- The UN agency for digital technologies
Digital Readiness Index (DRI) and its components: technology adoption and infrastructure	CISCO
Share of firms: owning website ; using foreign licensed technology; and with internationally recognised quality certificate	World Bank Enterprise Survey (WBES)
Human Capital (skill supply and health)	
Human Capital Index (HCI) and its components: learning adjusted years of school (LAYS), harmonized test scores (HLOS), and survival rate from age 15-60 (AMRT)	WDI
Compulsory education duration	WDI
School Enrolment rate, primary	WDI
School Enrolment rate, tertiary	WDI
Share of population between 15 and 64	WDI
Globalisation	
Share of ICT in Imported Goods	WDI
Foreign Direct Investment as % of GDP (FDI)	WDI
GVC participation (total, backward or forward) and exports	EORA (Lenzen et al., 2013, 2012)
Infrastructure	
Share of population with access to electricity	WDI
Urbanisation rate	WDI
Development	
Natural Logarithm of the GDP pc	WDI

Table 3. Control variables and data sources

Notes: Technology adoption (DRI component) includes: internet usage, mobile cellular subscriptions, and cloud services. Technology infrastructure (DRI component) includes: fixed broadband subscriptions, households' internet access, secure internet services, and mobile broadband subscriptions.

Source: own elaboration.

Given the cross-sectional nature of the regressions, the estimates are best interpreted as describing equilibrium allocations of AI-related tasks, rather than causal effects. Nonetheless, ICT intensity and firm characteristics

⁶ In cross-sectional setting, we cannot control for multiple development indicators at once.

are defined at the aggregate country-sector level and are plausibly exogenous to individual decisions. Human capital, while measured at the individual level, reflects pre-market factors such as education and cognitive skills.

To assess the relative importance of each factor, we use the estimated coefficients to compute a linear prediction of average AI exposure by country, \overline{AIE}_c , and apply the covariance-based decomposition proposed by Morduch and Sicular (2002). The contribution of a variable group, k, to the variance of AIE_c is given by:

$$\sigma_{k} = \frac{cov(\beta_{k}\bar{X}_{c}^{k}, \overline{AIE}_{c})}{var(\overline{AIE}_{c})}$$
(3)

Finally, to estimate AI exposure in countries lacking worker-level task data, we predict occupational AI exposure using OLS regressions estimated at the occupational level:

$$AIE_{kjc} = \beta_{j0} + \beta_{j1}GDP_c + \beta_{j2}\delta_c + \beta_{j3}T_c + \beta_{j4}H_c + \beta_{j5}G_c + \beta_{j6}I_c + \delta_c^{2022} + \gamma_{kj} + \varepsilon_{kjc}$$
(4)

where AIE_{kjc} is the AI exposure of occupation k, a 2-digit ISCO subcategory within 1-digit occupation j, in country c, GDP_c is GDP per capita, T_c , H_c , G_c , and I_c represent proxies for technology use, human capital, globalisation, and infrastructure, respectively; δ_c^{2022} is a fixed effect for observations based on the 2022-2023 surveys (PIAAC and CULS); and γ_{kj} are fixed effects for 2-digit occupations within a given 1-digit group.

This approach builds on Lewandowski et al. (2023), who estimated country-specific occupational routine task intensity conditional on development level and measures of technology adoption, skill supply, global value chains participation, and structural change. However, we use a broader set of variables to better capture technological capacity and human capital (see Table 3).

We estimate prediction models separately for 1-digit ISCO occupational groups, identify the optimal specification with a stepwise variable selection procedure. For each occupation, the estimation sample includes 69 country observations, of which 19 are covered in the 2022–2023 surveys and 15 are covered by two survey waves (14 countries with two cycles of PIAAC and China with two waves of CULS). To fit the models, for each country we use control variables pertaining to the period the relevant survey was taken. We predict occupational AI exposure for 70 countries, mostly low- and middle-income economies (Appendix Table A5), using the most recent available country-level indicators – typically from 2021–2022, except for GVC data from EORA (2015) and the ICT Development Index (2017).

First, we implement forward and backward selection methods across a range of p-value thresholds (0.01 to 0.5). Backward selection iteratively removes variables with p-values above the threshold, while forward selection adds variables whose p-values fall below it. Each model includes log GDP per capita and δ_c as baseline controls.

Second, we evaluate model performance using leave-one-out cross-validation (LOOCV). We estimate each model using all but one country and predict the excluded observation, repeating the process across the sample. For each 1-digit occupation, we retain the highest predictive accuracy model from both selection strategies. We use a maximum of seven explanatory variables to mitigate overfitting. We apply a variance-covariance decomposition of prediction and drop variables contributing the least to the explained variance. We also prioritise specific (e.g., learning-adjusted years of schooling) over composite indicators (e.g., the HCI), aiming for greater data-driven variability and interpretability.

Third, we re-run LOOCV to select the better-performing model from each forward-backward pair. We then augment these models with fixed effects for 2-digit occupations to allow predictions at a more granular occupational level. Table 4 lists the variables used in the final prediction models, and Appendix Table B9 reports the corresponding regression coefficients. The most frequently selected predictors of AI exposure include GDP per capita, share of population aged 15-64, urbanisation rate, university enrolment, the Digital Readiness Index, share of population using internet, technology infrastructure, and participation in global value chains (Table 4).

Variable	ISCO 1	ISCO 2	ISCO 3	ISCO 4	ISCO 5	ISCO 7	ISCO 8	ISCO 9
GDP pc	Х	Х	Х	Х	Х	Х	Х	Х
(GDP pc)^2	Х

3. Results

3.1. Descriptive evidence on cross-country differences in AI exposures

Adjusting AI exposure estimates for the cross-country differences in task composition reveals profound differences across the development spectrum (Figure 2). Comparing survey-based, country-specific AI exposures (right panel of Figure 2) with the globally applied AIOE index of Felten et al. (2021) (left panel), shows that incorporating country-specific task data amplifies cross-country variation beyond what is captured by occupational structure alone. While higher GDP per capita level is consistently associated with higher average AI exposure, the gradient is considerably steeper when using the task-adjusted, country-specific measure.

Under the original AIOE, the average AI exposure in the least developed countries is approximately 0.5 U.S. standard deviations below that of the United States—reflecting only differences in occupational composition. In contrast, the task-adjusted measure shows a gap of about one U.S. standard deviation, indicating that within-occupation task differences account for a substantial share of the exposure gap.

To validate this, we apply U.S.-based PIAAC-derived exposures to all countries and find results closely aligned with those from the original AIOE (Appendix Figure B4). This confirms that the observed differences between survey-based and AIOE-based exposures are driven by the use of country-specific task data—not by the substitution of PIAAC questions for O*NET abilities in the construction of AI exposure indices.

Note: Survey 2011-2018 includes the first cycle of PIAAC, STEP and 2016 CULS surveys. Survey 2022-2023 includes the second cycle of PIAAC and CULS 2023 surveys. The Spearman correlations between the AI exposure calculated with the most detailed information available in PIAAC/STEP and exposure calculated only with the set of questions and answers as available in STEP are 69% (country-level average) and 72% (country-occupation-level). AI exposures standardised with the US mean and standard deviation.

Source: Own calculations based on the O*NET, PIAAC, STEP and CULS data.

To quantify the respective contributions of occupational structure and task content to cross-country variation in AI exposure, we decompose the score for each country into three components. First, occupational structure: calculated using Felten et al. (2021) AIOE at the 2-digit ISCO level; variation reflects only differences in countries' occupational distributions at the 2-digit ISCO level⁷ (left panel of Figure 2). Second, task-related exposure: the difference between survey-based country-level exposure and exposure derived from applying U.S. PIAAC-based occupational scores to each country (difference between right panels of Figure 2 and Appendix Figure B3). Third, measurement change: the residual difference between U.S. PIAAC-based exposures and original AIOE exposures applied globally, capturing methodological differences in mapping AI to jobs between Felten et al. (2021), who used O*NET abilities, and our approach using PIAAC job tasks (difference between right and left panels of Appendix Figure B3).

⁷ For Austria, Canada, Estonia, Finland, and Philippines we use 1-digit ISCO due to data availability in PIAAC and STEP.

Task-related components contribute a noticeable share of countries' AI exposure (Figure 3). Using a variancecovariance decomposition (Morduch and Sicular, 2002), we find that they account for 49% of the cross-country variance in average AI exposure—nearly as much as differences in occupational structure (52%). The task component is particularly large in low- and middle-income countries (Figure 3). The measurement change contributes just 1% to the total variance, suggesting that methodological differences between PIAAC-based and O*NET-based mappings have minimal impact compared to actual variation in tasks and occupations.

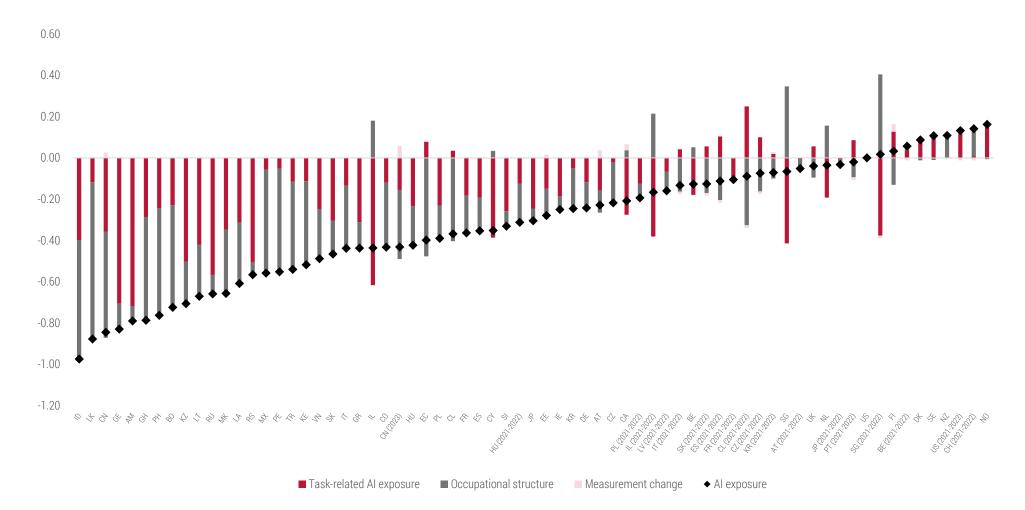

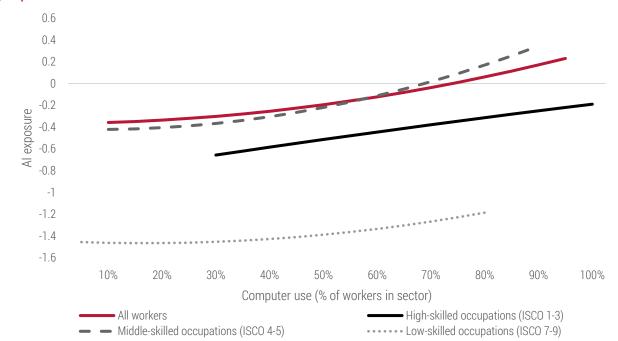

Figure 3. Decomposition of the differences in AI exposure by country

3.2. Determinants of worker-level AI exposure and cross-country differences

Estimating worker-level models of task-based AI exposure (Equation 2), we identify ICT intensity and socioeconomic characteristics as key correlates. Table 5 reports OLS estimates for the full sample (column 1) and for a subset of countries with occupational data at the 2-digit ISCO level (columns 2–3). Column 2 includes ISCO-1D fixed effects, consistent with column 1, while column 3 incorporates ISCO-2D fixed effects, capturing variation in AI exposure within more granular occupational categories.

Greater access to digital technologies is positively associated with AI exposure, particularly in country-sectors where over 50% of workers use computers (Figure 4). For example, a 17 pp increase in computer use– comparable to the gap between the U.S. (75%) and China (58%)–corresponds to a 0.11 standard deviation rise in AI exposure, equivalent to 29% of the U.S.–China differential in average exposure. This effect is most pronounced among workers in middle-skilled occupations (ISCO 4–5) who generally perform more structured and routine-intensive cognitive tasks than workers in high-skilled occupations (ISCO 1–3) and use computers less often. In middle-skilled occupations, even modest increases in computer use are linked to noticeable increases in AI exposure. Again, a 17 pp increase in computer use corresponds to 0.16 standard deviation rise in AI exposure among those occupations. In contrast, the relationship between computer use and AI exposure is relatively flat among workers in low-skilled occupations (ISCO 7–9), especially in country-sectors where less than 50% of workers use computers.

Note: Based on the estimates presented in Column 3 of Table 5. For each category of workers, we select a range of computer use which includes 90% of workers in each category (we omit bottom and top 5%). Median computer use among workers in occupations ISCO 1-3 is 73.5%, among ISCO 4-5 is 56.0%, and among ISCO 7-9 is 40.1%. Source: Own estimations based on PIAAC, STEP, WB, and EORA data.

Table 5. The correlates of individual AI exposures (OLS cross-country regression	on with occupational
controls	

Note: All regressions contain sector fixed effects (at 1-digit ISIC Rev.4 classification) and sector fixed effects interacted with GDP per capita. Base categories – Men, Primary education, aged 25-34, Lower-medium literacy proficiency (level 2). China is omitted due to data restrictions, Chile, Japan, Laos, Macedonia, Norway, Philippines, Sri Lanka, and Switzerland are omitted due to unavailability of some control variables. Austria (survey 2011-2018), Canada, Estonia, and Finland are omitted in columns (2) and (3) due to the lack of ISCO 2-digit occupations. Standard errors in parentheses. *** p<0.01, ** p<0.05, * p<0.1. Source: Own estimates based on PIAAC, STEP, WB, and EORA data. Human capital emerges as the strong predictor of AI exposure: higher levels of education and literacy proficiency are associated with significantly greater exposure (Table 5). For instance, a worker with the highest literacy proficiency (levels 4–5) is expected to have an AI exposure score 0.07 points higher than an otherwise similar worker with lower proficiency (level 2). This pattern aligns with previous (Cazzaniga et al., 2024; Comunale and Manera, 2024; Pizzinelli et al., 2023), which find that better-educated individuals are more exposed to AI. However, while those studies focus on differences between occupations, our worker-level approach demonstrates that this relationship persists within occupations, even within the 2-digit ISCO occupations (column 3 of Table 5). More skilled workers tend to perform more AI-exposed tasks, particularly those involving analytics and computer use, resulting in systematically higher exposure than their less skilled counterparts in the same occupations. Additionally, we find that women, as well as the youngest and oldest workers, are less exposed to AI than men and prime-aged workers in comparable occupations (Table 5).

Globalisation-linked characteristics of firms are also associated with AI exposure. In a country with average GDP per capita in our sample (e.g., South Korea or New Zealand), higher forward participation in global value chains (GVCs)—measured as the domestic value added embedded in partner countries' exports (Borin and Mancini, 2019, 2015)—is associated with lower AI exposure (Table 5, column 3). This is particularly relevant for many Sub-Saharan African and Latin American economies that specialise in upstream GVC tasks, such as commodity exports in agriculture and mining, with limited use of imported inputs (Hanson, 2017; Taglioni and Winkler, 2016). The interaction between forward GVC participation and GDP per capita is positive, indicating that the negative relationship weakens with higher income. Specifically, the effect disappears at double of the sample's average GDP per capita—approximately the level of France in 2022-2023—while it is more pronounced in low- and middle-income countries (LMICs). These findings are consistent with evidence that GVC-intensive work in LMICs is more routine-based (Lewandowski et al., 2024) and, as we show, less connected to advanced, AI-relevant tasks. Among other firm characteristics, adoption of modern tools such as websites is also positively associated with AI exposure.

Next, we use the estimated coefficients to assess the contributions of each group of explanatory variables to the countries' average AI exposure. We apply the covariance-based decomposition (Equation 3) to quantify their role in explaining cross-country differences. As the regressions control for 2-digit ISCO fixed effects, this decomposition sheds light on factors behind the within-occupation variation in AI exposure (Figure 3). Starting from the model using GDP per capita (Table 5, column 3), we re-estimate the specification substituting GDP with alternative development indicators to evaluate which dimensions are most strongly associated with variation in exposure.

Our models explain 81-84% of the cross-country variance in workers' AI exposure (Table 6). Across all specifications, ICT intensity is the dominant factor, accounting for 33-52% of the explained variance. Occupational structure contributes approximately 12.2%. Human capital—measured through education, literacy proficiency, gender, and age—explains about 10.7%, with the largest share (5.9%) attributable to literacy proficiency (detailed results available upon request). Observable, firm characteristics, related to firms adoption of modern tools such as websites and quality certificates, as well as the GVC position of the sector they are in, contribute between 3-5%.

In our baseline specification, GDP per capita contributes about 3.3% of the cross-country variance. When GDP is replaced with other indicators like Human Capital Index (13.1%) or learning adjusted years of schooling (10.6%), the contribution becomes larger (Table 6). It suggests that conditional on ICT intensity, human capital, and other explanatory variables, within-occupation, task-related differences are even more pronounced than according to differences in development levels. The development gradient in AI exposure, when measured through task differences within occupations, is stronger than would be expected based solely on income, technological infrastructure, or formal education metrics. Other development proxies, such as tertiary education enrolment, explain a smaller share of the cross-country variance (e.g., 1.7%).8

Overall, our findings highlight the central role of ICT infrastructure and digital technology use in shaping workers' Al exposure across countries at different development levels. They complement prior literature suggesting that more developed countries utilise skilled labour more efficiently by adopting technologies-such as ICT-that complement high-skill work (Caselli and Coleman, 2006) and that attributes international variation in skill premia mostly to cross-country differences in the skill bias of technology (Rossi, 2022)

⁸ We have also used development proxies used in out of sample predictions (see Table 4), such as the share of population with electricity, share of population using internet, school enrolment, technology adoption, technology infrastructure. For brevity, we do not present these results, they are available upon request.

3.3. Change in AI exposure between the early 2010s and the early 2020s

Next, we examine changes in workers' AI exposure between the early/mid 2010s and early 2020s, comparing results based on the first and the second PIAAC cycles.⁹ We use data for 14 countries, which, at the time of writing, provided data with 2-digit ISC008 occupations for both PIAAC cycles.

In all countries with available data, the average AI exposure increased, with the largest gains observed in lowertier high-income countries such as Slovakia, Chile, and Estonia. Notably, the initial level of AI exposure is strongly and negatively correlated with subsequent changes (correlation coefficient: -0.50), indicating convergence in exposure levels, at least among high-income economies with available data.

To unpack the mechanisms behind these changes, we again use a regression-based decomposition based on column 3 of Table 5, applied to changes in each country over time. ICT intensity emerges as the most important factor contributing to the rise in AI exposure (Figure 5). Time trend – secular increase in AI exposure across all countries and occupations covered by two waves of PIAAC data – is also noticeable. Its contribution is about half the size of that of ICT intensity. In contrast, changes in occupational structure contribute little, with France being the only minor exception. This suggests that countries experiencing greater increases in AI exposure did so largely through evolving job tasks within occupations rather than shifts in employment structure. Indeed, a shift-share decomposition indicates that within occupational change constitutes 90% of the average change in AI exposure over time in our sample. These findings further highlight the importance of using survey-based, task-level data that capture cross-country differences in the nature of work.

Note: Decomposition based on model 3 of Table 5. Computer use measures a share of workers using computers at country-sector level. Human capital includes worker-level education, literacy proficiency, gender, and age. Firm characteristics includes FDIs, backward and forward GVC participation and sector fixed effects. Development level is measured with country GDP per capita interacted with sector fixed effects. Occupational structure is controlled for 2-digit ISCO fixed effects. Time trend is a dummy variable indicating the second wave of the PIAAC study (2022-2023). Source: Own estimates based on PIAAC, WB, and EORA data.

⁹ For 10 out of 14 countries studied here, the first cycle PIAAC data were collected in 2011-2012 (BE, CZ, ES, FR, IT, JP, KR, PL, SK, US), for three in 2014-2015 (CL, IL, SG), and for one in 2017-2018 (HU).

3.4. Occupational AI exposures across the development spectrum

We now turn to occupation-level results, combining survey-based AI exposure estimates for 53 countries (16 of them observed in two survey waves) with regression-based predictions for 55 additional countries lacking task-level survey data. Appendix Table A5 lists all countries and their allocation into income groups: lower- and upper-tier high-income countries (HICs), upper-middle-income countries (UMICs), and low- and lower-middle-income countries (LMICs).¹⁰ While exposures are predicted at the 2-digit ISCO-08 level, we present results aggregated to the 1-digit level for clarity.

The predicted AI exposures replicate the development patterns observed in the survey data, consistent with the findings of Lewandowski et al. (2023), who used a similar methodology to predict routine task intensity in countries without the required survey data.

For each 1-digit ISCO-08 occupational group, our task-adjusted exposure measure shows considerably more cross-country variation than the AIOE index from Felten et al. (2021) (Figure 6). The variation in AIOE (left panels) arises solely from differences in the composition of 2-digit occupations within each 1-digit group. In contrast, our measure (right panels) incorporates cross-country differences in task content within occupations, offering a more nuanced picture. Note that the predicted values are for the 2020s and incorporate the estimated time trend in secular increase in AI exposure. In consequence, they are generally slightly above the trends present in the survey data which cover 37 countries surveyed in 2011-2018 and 16 surveyed in 2022-2023.

The greatest cross-country variation appears among high-skilled occupations (ISCO 1–3), including managers, professionals, and technicians. In these occupations, AI exposure rises clearly with GDP per capita, reflecting increased use of ICT-intensive tasks and greater ICT capital intensity in more developed countries. For middle-skilled occupations (ISCO 4–5), the relationship between GDP per capita and AI exposure is less pronounced. Exposure is relatively flat across much of the development spectrum, but increases sharply in the most advanced HICs, particularly Scandinavian countries. Notably, clerical support workers (ISCO 4) consistently exhibit the highest levels of AI exposure across all country groups, suggesting that this occupational group is likely to be globally affected by AI adoption. Among low-skilled occupations (ISCO 7–9), AI exposure also increases with development, although the gradient is less steep than for high-skilled workers. A notable exception is elementary occupations (ISCO 9), where no consistent relationship with GDP per capita emerges. Across low-skilled groups, average exposures are negative–i.e., lower than the U.S. mean–and consistently below those observed for high- and middle-skilled occupations.

¹⁰ Table 4 in subsection 2.4 provides the list of variables used in the prediction models and Table B9 in Appendix B shows the regression coefficients. We do not extrapolate beyond the range used to build the prediction models, specifically we do not predict AI exposures for countries with a GDP per capita below Kenya (\$2687 PPP, on average, between 2011 and 2016), the poorest country in the survey sample.

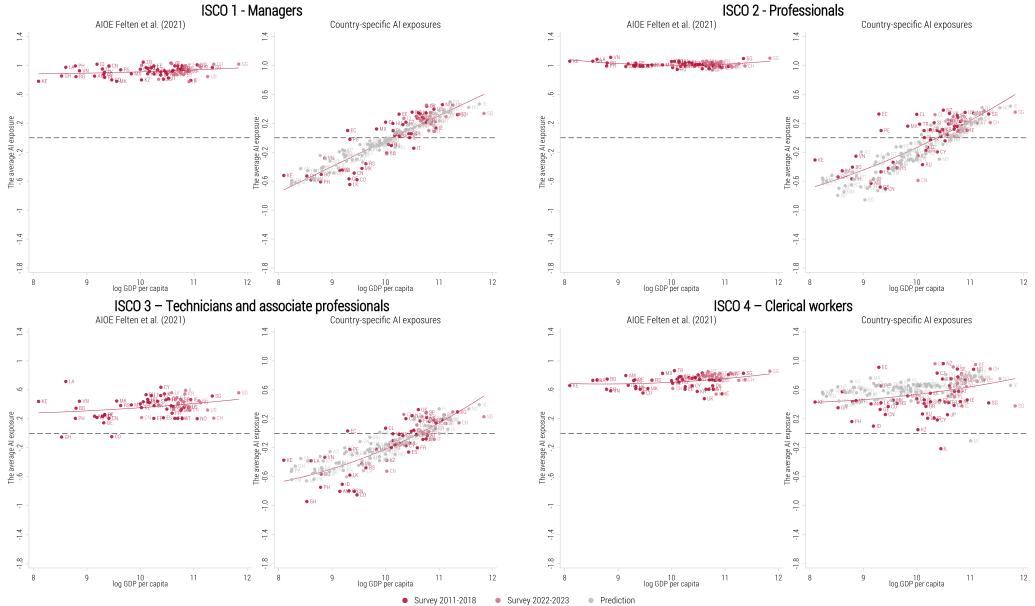

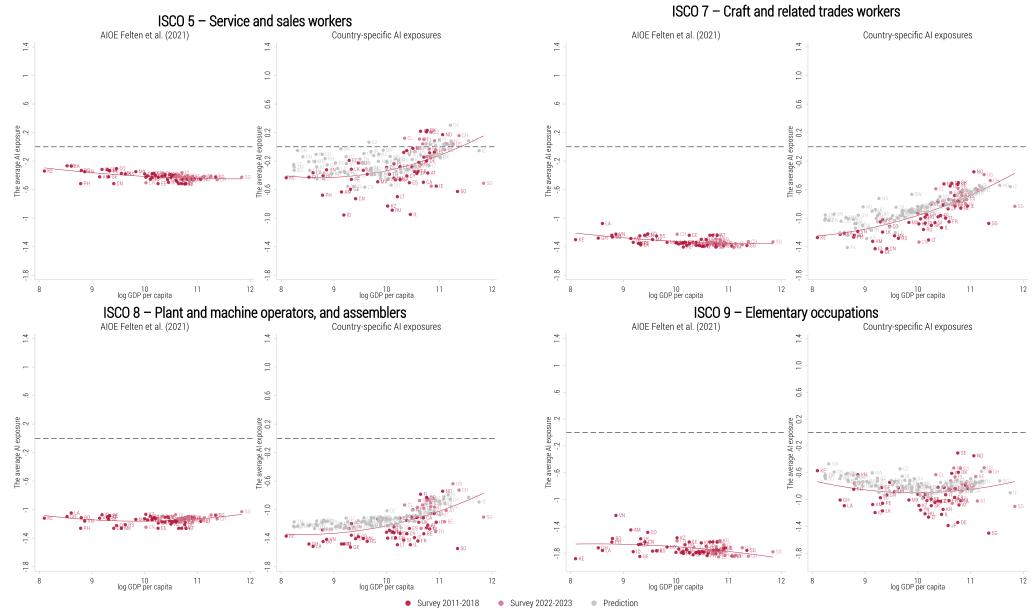

Figure 6. The comparison of the average Felten et al. (2021) and the PIAAC-based US AI exposures at the country level by ISCO-1d occupational groups and out-of-.sample prediction of AI exposures

Note: : Survey 2011-2018 includes the first cycle of PIAAC, STEP and 2016 CULS surveys. Survey 2022-2023 includes the second cycle of PIAAC and CULS 2023 surveys. The values of the AI exposures are standardised with the US mean and standard deviation.

Source: Own calculations based on PIAAC, STEP, WB, EORA, ITU, and CISCO data.

We next combine AI exposure estimates—both survey-based and predicted—with the most recent occupational structure data from the International Labour Organization (ILO). Our final dataset covers 94 countries (Appendix Table A5), representing approximately 89% of global employment.¹¹

Using AI exposures weighted by employment across all countries and occupations, we define the least exposed jobs as those in the bottom quartile (25th percentile) of the global AI exposure distribution and most exposed jobs as those in the top quartile (75th percentile).

High-income countries account for 29.9% of the world's most AI-exposed workers, but only 5.6% of the least exposed (Table 7). Upper-middle-income countries—including Brazil, China, and Turkey—host about 52.3% of the most and 34.7% of the least exposed workers. In contrast, low- and lower-middle-income countries, such as India, account for only 5.2% of the most exposed but half (53.3%) of the least exposed workers globally.

Table 7. Global distribution of the most/least Al-exposed workers, by country groups (in % of employment in a given category)

	Low or lower- middle income	Upper-middle income	Lower-tier high-income	Upper-tier high-income
Most exposed (top 25%)	5.2	52.3	12.5	29.9
Least exposed (bottom 25%)	53.3	34.7	6.4	5.6
Total employment	40.2	34.0	8.4	17.5

Note: Country group classifications follow Appendix Table A5.

Source: Own calculations based on PIAAC, STEP, WB, EORA, ITU, CISCO, and ILO data.

As a result, countries with the highest shares of highly AI-exposed workers are predominantly high-income economies. In contrast, major emerging markets such as China and India have comparatively low shares of highly exposed workers. Meanwhile, upper-middle-income countries (e.g., Brazil, Mexico) and lower-middle-income countries (e.g., Indonesia, the Philippines) record the highest employment shares of workers in the least exposed category globally.

4. Conclusions

This paper presents a task-adjusted, country-specific measure of workers' AI exposure across a wide range of development contexts. Adapting the widely used AIOE index by Felten et al., (2021) to U.S. PIAAC data, we constructed a worker-level AI exposure metric. We then extended this measure to 53 countries using comparable survey data and developed regression-based predictions for 55 more countries without survey coverage, providing exposures for 108 countries. Combining AI exposures with available employment data for 94 countries our analysis covers approximately 89% of global employment.

A central finding is that accounting for worker-level tasks is essential to understanding AI exposure. Doing so reveals significant cross-country heterogeneity, particularly along the development spectrum. On average,

¹¹ We exclude tax heavens, petrostates, island countries, and countries without credible employment data.

workers in low-income countries experience AI exposure levels roughly one U.S. standard deviation below those in high-income countries. Half of this cross-country variation is attributable to differences in occupational task content. This variation is especially pronounced among high-skilled occupations, where workers typically engage in more abstract, non-routine tasks—activities that vary widely across countries depending on technological capacity, skill supply, and positions in global value chains (Caunedo et al., 2023; Lewandowski et al., 2022). By contrast, AI exposure among medium- and low-skilled occupations shows little development gradient, as relevant job tasks vary less systematically across the GDP per capita spectrum.

Using regression-based decompositions, we attribute most of cross-country variation in AI exposure to differences in the intensity of ICT in the economy and its technological capabilities. We also find that AI exposure is positively associated with workers' education and skill levels: more educated and higher-skilled individuals consistently report greater exposure to AI-related tasks. When quantifying global variation, high-income countries host the largest share of workers in highly AI-exposed occupations, while low-income countries concentrate a much greater share of workers in less exposed roles. Emerging economies such as China and India show relatively low average AI exposure, whereas countries like Brazil, Mexico, Indonesia, and the Philippines have a large proportion of workers in occupations with minimal AI exposure.

For the subset of high-income countries with two waves of PIAAC data, we find a clear increase in AI exposure between the early 2010s and early 2020s, almost entirely driven by within-occupation changes in task composition. This further highlights the importance of capturing task structures in exposure assessments.

Understanding variation in AI exposure across occupations and countries has important policy implications. Advanced economies—where AI-exposed workers are most concentrated—are likely to face both the opportunities and disruptions of AI adoption earlier and more intensively (Cazzaniga et al., 2024). However, widespread displacement is unlikely to occur rapidly, as the automation of highly exposed tasks remains constrained by cost and feasibility (Svanberg et al., 2024). The development gradient of skill-biased of technologies such as ICT has been cited as a driven of cross-country differences in returns to skills (Caselli and Coleman, 2006; Rossi, 2022). Our findings suggest that in the context of AI, these pre-existing differences in ICT adoption may exacerbate existing economic and technological disparities as emerging economies will likely face challenges in adopting AI due to limited digital infrastructure and technological readiness.

A limitation of our exposure-focused approach is that we do not determine whether AI will complement or substitute human labour. While this distinction is of key importance, we believe it should be assessed based on empirical evidence on the actual AI adoption rather than arbitrary assumptions about the extent of substitutability of particular tasks or their bundles, as would be required in our approach.

Appendix A – Technical details

Table A1. The list of O*NET abilities

Abilities approximated with	PIAAC/ STEP:
	The ability to focus on a single source of sound in the presence of other distracting
auditory attention	sounds.
	The ability to generate or use different sets of rules for combining or grouping things
category flexibility	in different ways.
	The ability to apply general rules to specific problems to produce answers that make
deductive reasoning	sense.
	The ability to identify or detect a known pattern (a figure, object, word, or sound) that
flexibility of closure	is hidden in other distracting material.
	The ability to come up with a number of ideas about a topic (the number of ideas is
fluency of ideas	important, not their quality, correctness, or creativity).
	The ability to combine pieces of information to form general rules or conclusions
inductive reasoning	(includes finding a relationship among seemingly unrelated events).
-	The ability to arrange things or actions in a certain order or pattern according to a
	specific rule or set of rules (e.g., patterns of numbers, letters, words, pictures,
information ordering	mathematical operations).
mathematical reasoning	The ability to choose the right mathematical methods or formulas to solve a problem.
5	The ability to remember information such as words, numbers, pictures, and
memorisation	procedures.
number facility	The ability to add, subtract, multiply, or divide quickly and correctly.
	The ability to listen to and understand information and ideas presented through
oral comprehension	spoken words and sentences.
ordi comprenencion	The ability to communicate information and ideas in speaking so others will
oral expression	understand.
orarexpression	The ability to come up with unusual or clever ideas about a given topic or situation, or
originality	to develop creative ways to solve a problem.
originality	The ability to quickly and accurately compare similarities and differences among sets
	of letters, numbers, objects, pictures, or patterns. The things to be compared may be
	presented at the same time or one after the other. This ability also includes
perceptual speed	comparing a presented object with a remembered object.
perceptual specu	The ability to tell when something is wrong or is likely to go wrong. It does not involve
problem sensitivity	solving the problem, only recognising that there is a problem.
selective attention	The ability to concentrate on a task over a period of time without being distracted.
speech clarity	The ability to speak clearly so others can understand you.
speech recognition	The ability to identify and understand the speech of another person.
anad of alagura	The ability to quickly make sense of, combine, and organise information into
speed of closure	meaningful patterns. The chilitate current constant of the second second second sectors with such methics.
at a second s	The ability to exert yourself physically over long periods of time without getting
stamina	winded or out of breath.
	The ability to shift back and forth between two or more activities or sources of
time sharing	information (such as speech, sounds, touch, or other sources).
	The ability to imagine how something will look after it is moved around or when its
visualisation	parts are moved or rearranged.
written comprehension	The ability to read and understand information and ideas presented in writing.
written expression	The ability to communicate information and ideas in writing so others will understand.

Abilities that cannot be approximated with PIAAC/ STEP data

Abilities that cannot be approx	ximated with PIAAC/ STEP data
arm-hand steadiness	The ability to keep your hand and arm steady while moving your arm or while holding your arm and hand in one position.
	The ability to quickly and repeatedly adjust the controls of a machine or a vehicle to
control precision	exact positions. The ability to judge which of several objects is closer or farther away from you, or to
depth perception	judge the distance between you and an object.
dynamic flexibility	The ability to quickly and repeatedly bend, stretch, twist, or reach out with your body, arms, and/or legs.
dynamic strength	The ability to exert muscle force repeatedly or continuously over time. This involves muscular endurance and resistance to muscle fatigue.
dynamic strengtri	The ability to use short bursts of muscle force to propel oneself (as in jumping or
explosive strength	sprinting), or to throw an object.
extent flexibility	The ability to bend, stretch, twist, or reach with your body, arms, and/or legs.
far vision	The ability to see details at a distance.
	The ability to make precisely coordinated movements of the fingers of one or both
finger dexterity	hands to grasp, manipulate, or assemble very small objects.
glare sensitivity	The ability to see objects in the presence of a glare or bright lighting.
giare benoitivity	The ability to coordinate the movement of your arms, legs, and torso together when
gross body coordination	the whole body is in motion.
gross body coordination	•
	The ability to keep or regain your body balance or stay upright when in an unstable
gross body equilibrium	position.
	The ability to detect or tell the differences between sounds that vary in pitch and
hearing sensitivity	loudness.
	The ability to quickly move your hand, your hand together with your arm, or your two
manual dexterity	hands to grasp, manipulate, or assemble objects.
	The ability to coordinate two or more limbs (for example, two arms, two legs, or one
	leg and one arm) while sitting, standing, or lying down. It does not involve performing
multilimb coordination	the activities while the whole body is in motion.
near vision	The ability to see details at close range (within a few feet of the observer).
night vision	The ability to see under low-light conditions.
	The ability to see objects or movement of objects to one's side when the eyes are
peripheral vision	looking ahead.
	The ability to time your movements or the movement of a piece of equipment in
rate control	anticipation of changes in the speed and/or direction of a moving object or scene.
	The ability to quickly respond (with the hand, finger, or foot) to a signal (sound, light,
reaction time	picture) when it appears.
	The ability to choose quickly between two or more movements in response to two or
	more different signals (lights, sounds, pictures). It includes the speed with which the
response orientation	correct response is started with the hand, foot, or other body part.
sound localisation	The ability to tell the direction from which a sound originated.
	The ability to know your location in relation to the environment or to know where
spatial orientation	other objects are in relation to you.
speed of limb movement	The ability to quickly move the arms and legs.
static strength	The ability to exert maximum muscle force to lift, push, pull, or carry objects.
statio strength	The ability to use your abdominal and lower back muscles to support part of the body
truply atropath	
trunk strength	repeatedly or continuously over time without "giving out" or fatiguing.
	The ability to match or detect differences between colours, including shades of colour
visual colour discrimination	and brightness.
	The ability to make fast, simple, repeated movements of the fingers, hands, and
wrist-finger speed	wrists.

Table A2. The list of occupations, ISC008 2-digits

Source: own elaboration.

Task item	PIAAC			STEP			
	Question	Ans	swers	Question	An	swers	
Changing order	Are you allowed to change the sequence of your tasks?	1. 2. 3. 4. 5.	Not at all Very little To some extent To a high extent To a very high extent	Still thinking of your work [OCCUPATION] how much freedom do you have to decide how to do your work in your own way, rather than following a fixed procedure or a supervisor's instructions? Use any number from 1 to 10 where 1 is no freedom and 10 is complete freedom.	1-10		
Complex problems	And how often are you usually confronted with more complex problems that take at least 30 minutes to find a good solution? The 30 minutes only refers to the time needed to THINK of a solution, not the time needed to carry it out.	1. 2. 3. 4.	Never Less than once a month Less than once a week but at least once a month At least once a week but not every day Every day	Some tasks are pretty easy and can be done right away or after getting a little help from others. Other tasks require more thinking to figure out how they should be done. As part of this work as [OCCUPATIION], how often do you have to undertake tasks that require at least 30 minutes of thinking (examples: mechanic figuring out a car problem, budgeting for a business, teacher making a lesson plan, restaurant owner creating a new menu/dish for restaurant, dressmaker designing a new dress).	1. 2. 3. 4.	Never Less than once a month Less than once a week but at least once a month At least once a week but not every day Every day	
Physical	How often are you usually working physically for a long period?	As abov	e	Using any number from 1 to 10 where 1 is not at all physically demanding (such as sitting at desk answering telephone) and 10 is extremely physically demanding(such as carrying heavy loads, construction worker, etc.), what number would you use to rate how physically demanding your work is?	1-10		
	In your job, how often are you usually			As a regular part of this work, do you have to			

Table A3. Task items, corresponding questions and possible answers in PIAAC and STEP surveys

Read news	reading articles in newspapers, magazines or newsletters?	As above	read newspapers or magazines?	Yes/ No
Read professional	reading articles in professional journals or scholarly publications?	As above	read reports?	As above
Fill forms	filling in forms?	As above	fill out bills or forms?	As above
Read	reading manuals or	As above	read instruction manuals/	As above
manuals	reference materials?		operating manuals?	
Presenting	How often does your job usually involve making speeches or giving presentations in front of five or more people?	As above	As part of this work, do you have to make formal presentations to clients or collegues to provide information or persuade them of your point of view?	As above
	In your job, how often do you usually		As a normal part of this work, do you do any of the following?	
Use advanced math	use more advanced math or statistics such as calculus, complex algebra, trigonometry or use of regression techniques?	As above	use more advanced math, such as algebra, geometry, trigonometry, etc.	As above
Calculate prices	calculate prices, costs or budgets?	As above	calculate prices or costs	As above
Use programming	In your job, how often are you usually using a programming language to program or write computer code?	As above	Does your work as [OCCUPATION] require the use of software programming?	As above
Use email	In your job, how often do you usually use email?	As above	Does your work as [OCCUPATION] require the use email?	As above
Use spreadsheets	In your job, how often do you usually use spreadsheet software, for example Excel?	As above	Does your work as [OCCUPATION] require the use spreadsheets (such as Excel)?	As above
Supervising	Do you manage or supervise other employees?	As above	As a normal part of this work do you direct and check the work of other workers (supervise)?	As above
Time	How often does your job usually involve planning your own activities?	As above	- N/A	
managing	How often does your job usually involve organising your own time?	As above

Jamaica Malaysia Mauritius Montenegro Namibia Romania South Africa Thailand	Croatia Uruguay	Australia Iceland Luxembourg

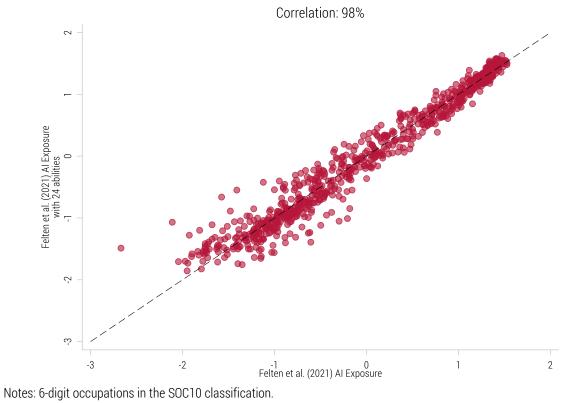

Table A5: Allocation of countries to income groups

Notes: the allocation of countries to low- and lower middle-, upper middle-, and high-income groups follows the World Bank Analytical Classification. The additional split of high-income countries to the lower- and upper-tier subgroups follows Lewandowski et al. (2022). Table includes only countries with available employment data. 1- STEP/CULS. 2-PIAAC 2011-2018, 3- PIAAC 2022-2023. Countries with AI exposures but without employment data are: Angola, Argentina, Benin, Colombia, Cyprus, Gabon, Guinea, Jordan, Malta, Nicaragua, Nigeria, Senegal, Tunisia, Uzbekistan.

Source: authors' elaboration based on World Bank data.

Appendix B – Additional results

Figure B1 . Correlation between AIOE and AIOE calculated on a restricted sample of abilities

Source: own elaboration based on Felten et al. (2021)

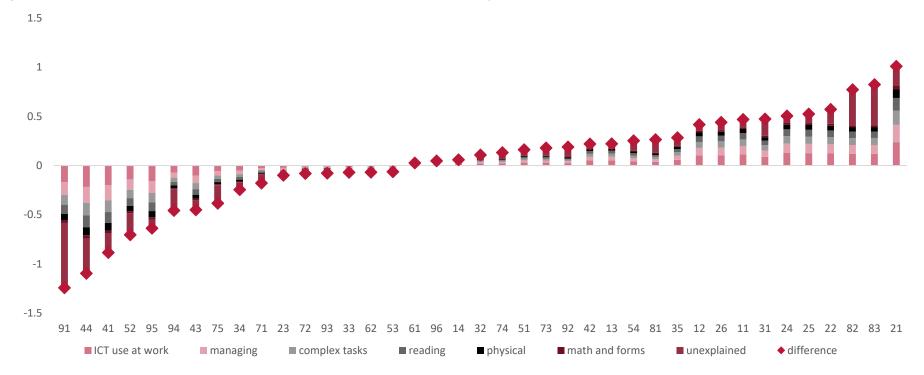

Figure B2. Decomposition of difference between Felten and PIAAC-based exposures, by PIAAC questions

Source: own elaboration based on PIAAC and O*NET data.

Note: : We use variance-covariance decomposition (Morduch and Sicular, 2002). The unexplained difference is the difference attributed to O*NET abilities that cannot be approximated with PIAAC. For the list of occupations, see Table A2 in the Appendix A.

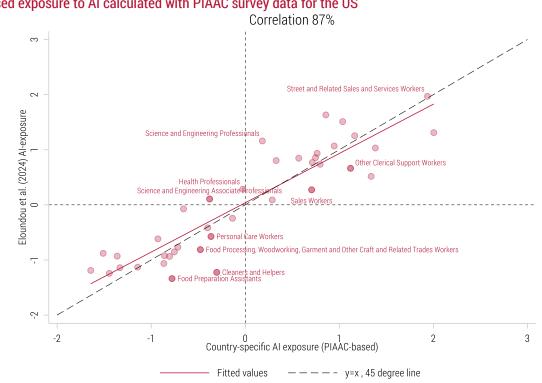

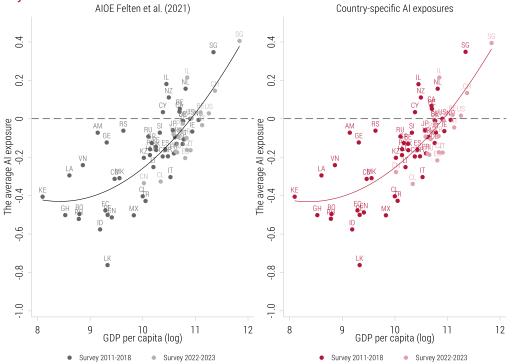

Figure B3. The correlation between occupational exposure to GPTs (Eloundou et al., 2024) and taskbased exposure to AI calculated with PIAAC survey data for the US

Note: We use GPT exposures based on human ratings (Eloundou et al., 2024). Source: own elaboration based on Eloundou et al. (2024) and PIAAC data.

Note: AI exposures standardised with the US mean and standard deviation. Source: Own elaboration based on PIAAC, STEP, WB, EORA, ITU and CISCO data.

Within-country variance decomposition of worker-level AI exposure

This section assesses the importance of each question used in the study, decomposing a within-country variance in individual AI exposures. In other words, we calculate the share of variance in AI exposure explained by each question. Each question represents different skills required to perform occupations. We will refer to them as skill categories (see Table B1 for a list and corresponding questions).

Regarding PIAAC data, except *supervision* (dummy variable), each skill component takes values from 1 to 5 (categorical variable). See Table 1 for the list of questions used to approximate each ability required to perform each occupation.

In the case of STEP data, *physical, changing order* and *complex problems* take values from 1 to 5, and the rest are dummy variables (see Table 2 for the list of used questions). We use all available information (all skill components) to approximate each ability required to perform each occupation.

ICT use at work is the most important factor among PIAAC countries and explains, on average, 28% of the variance (see Figure B5). *Managing, solving complex problems* and *reading* explains 21%, 20% and 15% of the variance, respectively. *Physical* (9%) and *math and forms* (4%) skill categories are less important.

In the case of the STEP countries *managing* (161%) and *reading* (-59%) are the most important skill categories explaining the variance in the AI exposure. *Solving complex problems* (10%), *ICT use at work* (-7%), *physical* (-4%) *and math and forms* (-1%) are far less relevant,

Skill category	How many times used? (PIAAC)	Variance explained in US PIAAC (%)	Used in:	Question number	Complete question
ICT use at work	23	22.2%	PIAAC/ STEP	Q16	In your job, how often do you usually use email?
reading	22	18.3%	PIAAC/ STEP	Q7	And how often are you usually confronted with more complex problems that take at least 30 minutes to find a good solution? The 30 minutes only refers to the time needed to THINK of a solution, not the time needed to carry it out.
reading	20	9.7%	PIAAC	Q5	How often does your job usually involve planning your own activities?
ICT use at work	20	9.1%	PIAAC/ STEP	Q8	How often does your job usually involve working physically for a long period?
physical	19	7.7%	PIAAC/ STEP	Q9	In your job, how often do you usually read articles in newspapers, magazines or newsletters?
managing	16	7.6%	PIAAC	Q6	How often does your job usually involve organising your own time?
complex tasks	14	6.2%	PIAAC/ STEP	Q17	In your job, how often do you usually use spreadsheet software, for example Excel?
managing	11	4.6%	PIAAC/ STEP	Q13	In your job, how often do you usually fill in forms?

Table B1. The list of questions used in the calculation of individual AI exposures, usage frequency and the share of explained within-country variance

managing	8	4.6%	PIAAC/ STEP	Q10	In your job, how often do you usually read articles in professional journals or scholarly publications?
reading	4	3.8%	PIAAC/ STEP	Q11	In your job, how often do you usually read manuals or reference materials?
math and forms	4	3.5%	PIAAC/ STEP	Q4	How often does your job usually involve making speeches or giving presentations in front of five or more people?
managing	2	2.0%	PIAAC/ STEP	Q3	In your job, what proportion of your time do you usually spend cooperating or collaborating with co-workers?
math and forms	2	0.2%	PIAAC/ STEP	Q1	Do you manage or supervise other employees?
managing	1	0.2%	PIAAC/ STEP	Q15	In your job, how often do you usually use more advanced math or statistics such as calculus, complex algebra, trigonometry or use of regression techniques?
reading	1	0.1%	PIAAC/ STEP	Q14	In your job, how often do you usually calculate prices, costs or budgets?
math and forms	1	0.1%	PIAAC/ STEP	Q18	In your job, how often do you usually use a programming language to program or write computer code?
ICT use at work	1	0.1%	PIAAC/ STEP	Q12	In your job, how often do you usually read bills, invoices, bank statements or other financial statements?
managing	0	0.0%	PIAAC/ STEP	Q2	To what extent can you choose or change the sequence of your tasks?

Source: Own elaboration based on PIAAC and STEP data.

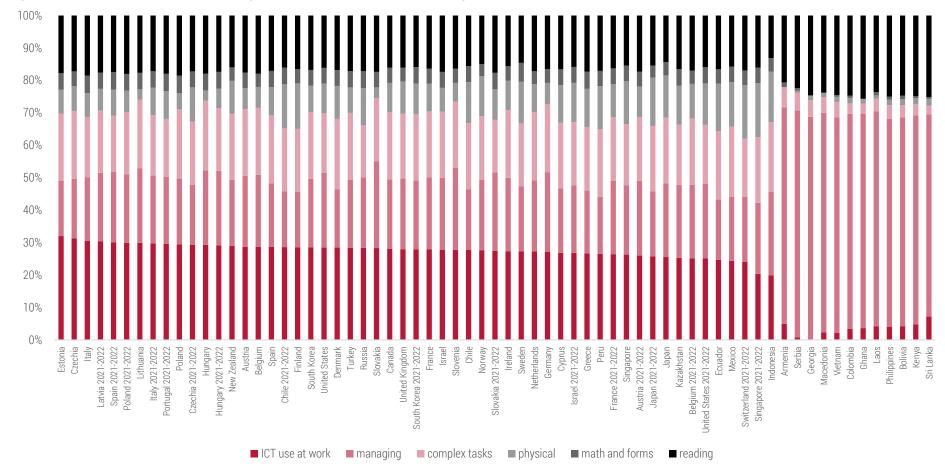

Figure B5. Decomposition of within-country variance in AI exposure to skill categories

Notes: We use variance-covariance decomposition (Morduch and Sicular, 2002). For the list of task items and Its correspondence with the PIAAC/ STEP questions see Table A3 in the Appendix A. Countries sorted according to ICT use at work. Contributions of skill categories across STEP countries are rescaled to sum to 100%. Source: own elaboration.
